

METHOD AND SYSTEM FOR GLOBAL LOG ON IN A DISTRIBUTED SYSTEM

ABSTRACT

A distribution system for distributing content for a medical information collection system. The collection system comprises a collection server and multiple collection kiosks. A collection kiosk is a computer system attached to various devices for collecting medical information. The collection kiosks may be located at various locations, such as in drug stores or pharmacies. A person can use the collection kiosks to collect and store their medical information. The collection kiosks may have a user interface through which a person can enter a user identifier and password to obtain access to their stored medical information. Whenever a user wants to collect current medical information, the user would go to a collection kiosk, log on to the kiosk, and have their medical information collected and then stored.
